

TCP with lossy channel

Segment loss probability $q = 1 - p$
 Throughput T
 Threshold w , Bandwidth B

usually in congestion mode

Equilibrium

2) # succ. transmissions $\hat{8} + (S/2)^2 + (S/2)^2 + \dots + 2S = S \cdot \frac{5^2}{2}$
 Δ careful explanation.

1) # succ. transmissions $\sum_{i=0}^{\infty} i \cdot p^i (1-p) = \frac{p}{1-p} = p/q. =: E$

$$\frac{1}{4} S^2 = E \Leftrightarrow S = \sqrt{2E}$$

$$T = \frac{1}{2} S = \sqrt{\frac{1}{2} E} = \sqrt{\frac{1}{2} \frac{p}{q}}$$

We are interested in $p \rightarrow 1$ ($q < 0.1$)

$$\Rightarrow T(p) = \Theta(1/\sqrt{q})$$

$$\Delta T(p) \leq B \Rightarrow T(p) = \min(B, \sqrt{\frac{1}{2} \frac{p}{q}})$$
