- HSCSD, GPRS

Mobile phones worldwide

Mobile phone subscribers worldwide

Distributed Computing Group
MOBILE COMPUTING
R. Wattenhofer
**GSM: Overview**

- formerly: Groupe Spéciale Mobile (founded 1982)
- now: Global System for Mobile Communication
- Pan-European standard (ETSI, European Telecommunications Standardization Institute)
- simultaneous introduction of essential services in three phases (1991, 1994, 1996) by the European telecommunication administrations
- seamless roaming within Europe possible
- today many providers all over the world use GSM (more than 135 countries in Asia, Africa, Europe, Australia, America)
- more than 640 million subscribers

**Performance characteristics of GSM**

- **Communication**
  - mobile, wireless communication; support for voice and data services
- **Total mobility**
  - international access, chip-card enables use of access points of different providers
- **Worldwide connectivity**
  - one number, the network handles localization
- **High capacity**
  - better frequency efficiency, smaller cells, more customers per cell
- **High transmission quality**
  - high audio quality and reliability for wireless, uninterrupted phone calls at higher speeds (e.g., from cars, trains)
- **Security functions**
  - access control, authentication via chip-card and PIN

**Disadvantages of GSM**

- no end-to-end encryption of user data
- no full ISDN bandwidth of 64 kbit/s to the user
- reduced concentration while driving
- electromagnetic radiation
- abuse of private data possible
- roaming profiles accessible
- high complexity of the system
- several incompatibilities within the GSM standards

**GSM: Mobile Services**

- GSM offers
  - several types of connections: voice connections, data connections, short message service
  - multi-service options (combination of basic services)
- Three service domains
  - Bearer Services
  - Telematic Services
  - Supplementary Services
Bearer Services

- Telecommunication services to transfer data between access points
- Specification of services up to the terminal interface (OSI layers 1-3)
- Different data rates for voice and data (original standard)

- data service (circuit switched)
  - synchronous: 2.4, 4.8 or 9.6 kbit/s
  - asynchronous: 300 - 1200 bit/s

- data service (packet switched)
  - synchronous: 2.4, 4.8 or 9.6 kbit/s
  - asynchronous: 300 - 9600 bit/s

Tele Services

- Telecommunication services that enable voice communication via mobile phones
- All these basic services have to obey cellular functions, security measurements etc.

- Offered services
  - mobile telephony
    primary goal of GSM was to enable mobile telephony offering the traditional bandwidth of 3.1 kHz
  - Emergency number
    common number throughout Europe (112); mandatory for all service providers; free of charge, without contract; connection with the highest priority (preemption of other connections possible)

Additional Tele Services

- Non-Voice-Teleservices
  - Short Message Service (SMS)
    up to 160 character alphanumeric data transmission to/from the mobile terminal using the signaling channel, thus allowing simultaneous use of basic services and SMS
  - group 3 fax
  - voice mailbox (implemented in the fixed network supporting the mobile terminals)
  - electronic mail (MHS, Message Handling System, implemented in the fixed network)
  - etc.

Supplementary services

- Services in addition to the basic services, cannot be offered stand-alone
- Similar to ISDN services besides lower bandwidth due to the radio link
- May differ between different service providers, countries and protocol versions
- Important services
  - identification: forwarding of caller number
  - suppression of number forwarding
  - automatic call-back
  - conferencing with up to 7 participants
  - locking of the mobile terminal (incoming or outgoing calls)
  - etc.
GSM: overview

- OMC, EIR, AUC
- HLR
- GMSC
- VLR
- MSC
- BSC

fixed network

Architecture of the GSM system

- GSM is a PLMN (Public Land Mobile Network)
- several providers setup mobile networks following the GSM standard within each country
- components
  - MS (mobile station)
  - BS (base station)
  - MSC (mobile switching center)
  - LR (location register)
- subsystems
  - RSS (radio subsystem): covers all radio aspects
  - NSS (network and switching subsystem): call forwarding, handover, switching
  - OSS (operation subsystem): management of the network

GSM: elements and interfaces

- OMC, EIR, AUC
- HLR
- GMSC
- VLR
- MSC
- BSC

BTS

BSC MSC

BTS

BSC

BTS

BSS

radio cell

network and switching subsystem

System architecture: radio subsystem

- Components
  - MS (Mobile Station)
  - BSS (Base Station Subsystem): consisting of
    - BTS (Base Transceiver Station): sender and receiver
    - BSC (Base Station Controller): controlling several transceivers
- Interfaces
  - $U_m$: radio interface
  - $A_{16k}$: standardized, open interface with 16 kbit/s user channels
  - $A$: standardized, open interface with 64 kbit/s user channels
Base Transceiver Station and Base Station Controller

- Tasks of a BSS are distributed over BSC and BTS
- BTS comprises radio specific functions
- BSC is the switching center for radio channels

Mobile station

- Terminal for the use of GSM services
- A mobile station (MS) comprises several functional groups
  - MT (Mobile Terminal):
    - offers common functions used by all services the MS offers
    - corresponds to the network termination (NT) of an ISDN access
    - end-point of the radio interface ($U_m$)
  - TA (Terminal Adapter):
    - terminal adaptation, hides radio specific characteristics
  - TE (Terminal Equipment):
    - peripheral device of the MS, offers services to a user
    - does not contain GSM specific functions
  - SIM (Subscriber Identity Module):
    - personalization of the mobile terminal, stores user parameters

System architecture: network and switching subsystem

- MSC (Mobile Services Switching Center)
  - IWF (Interworking Functions)
  - ISDN (Integrated Services Digital Network)
  - PSTN (Public Switched Telephone Network)
  - PSPDN (Packet Switched Public Data Net.)
  - CSPDN (Circuit Switched Public Data Net.)
- Databases
  - HLR (Home Location Register)
  - VLR (Visitor Location Register)
  - EIR (Equipment Identity Register)

System architecture: operation subsystem

- The OSS (Operation Subsystem) enables centralized operation, management, and maintenance of all GSM subsystems
- Components
  - Operation and Maintenance Center (OMC)
    - different control capabilities for the radio subsystem and the network subsystem
  - Authentication Center (AuC)
    - generates user specific authentication parameters on request of a VLR
    - authentication parameters used for authentication of mobile terminals and encryption of user data on the air interface within the GSM system
  - Equipment Identity Register (EIR)
    - registers GSM mobile stations and user rights
    - stolen or malfunctioning mobile stations can be locked and sometimes even localized
GSM: system architecture

- Radio subsystem
- Network and switching subsystem
- Fixed partner networks

- MS
- BTS
- BSC

- ISDN
- PSTN

- IWF

- ISDNPSTN
- PSPDN
- CSPDN

Example for space multiplexing: Cellular network

- Simplified hexagonal model
- Signal propagation ranges
- Frequency reuse only with a certain distance between the base stations
- Can you reuse frequencies in distance 2 or 3 (or more)?
- Graph coloring problem
- Example: fixed frequency assignment for reuse with distance 2
- Interference from neighbor cells (other color) can be controlled with transmit and receive filters

GSM: cellular network

- Segmentation of the area into cells
- Possible radio coverage of the cell
- Idealized shape of the cell
- Use of several carrier frequencies
- Not the same frequency in adjoining cells
- Cell sizes vary from some 100 m up to 35 km depending on user density, geography, transceiver power etc.
- Hexagonal shape of cells is idealized (cells overlap)
- If a mobile user changes cells: handover of the connection to the neighbor cell

Channel Assignment

- Formal definition of the problem:
  - Input: A graph G, the nodes of G are the cells, there is an edge between two nodes if the cells interfere. Each node u has an integer weight w(u) that represents the number of users in cell u.
  - Output: We assign w(u) colors to each node, such that no two neighboring nodes have the same color. We are interested in the minimum number of colors needed.
  - This problem known as Graph Multicoloring. It is NP-hard.
Channel Assignment Variations

- Special types of graphs, e.g. the hexagon graph.
- Dynamic version: the weight of a node \( w_t(u) \) is a function that changes over time. If a future \( w_t(u) \) is not known, the algorithm is online.
- Recoloring vs. non-recoloring algorithms: A dynamic algorithm is a non-recoloring algorithm if the frequency of a user is not allowed to change once it is assigned. Note that a recoloring algorithm is more powerful.
- Centralized vs. Distributed Control. In particular, an algorithm is \( k \)-local if each node can only communicate with nodes within distance \( k \).

Basic Types of Algorithms

- Fixed Assignment (FA): Nodes are partitioned into independent sets, and each such set is assigned a separate set of channels. This works very well if the traffic is balanced well. Example: Hexagon graph with reuse distance 3 is on the right.
- Borrowing Algorithms: Improvement of FA. If traffic is not balanced, cells can borrow frequencies from neighboring cells.
- Hybrid Channel Assignment: Divide the frequencies into “reserved” and “borrowable” ones.
- Dynamic Channel Assignment: A centrally coordinated pool of frequencies is distributed to cells.

Online Channel Assignment

- Problem: We are given the hexagon graph with reuse distance 2. Callers arrive at cells in online fashion, that is, one after the other in an input sequence \( \sigma \). We need to give each caller a channel (an integer), such that no caller in the same or a neighboring hexagon has the same channel. We assume that calls have infinite duration (which is the same as assuming that all calls have the same duration).
- Cost: The cost of the algorithm is the value of the highest channel we used.
- Competitive Analysis: If \( \text{cost}_{\text{ALG}}(\sigma) \leq \rho \cdot \text{cost}_{\text{OPT}}(\sigma) + \text{const} \) for all input sequences \( \sigma \) and an optimal offline algorithm OPT, then the Algorithm ALG is called \( \rho \)-competitive. (Note: if \( \text{const} = 0 \) the ALG is strictly \( \rho \)-competitive.)

The Greedy Algorithm for Online Channel Assignment

- Algorithm: When a new call arrives, it is assigned the minimum available channel, that is, the minimum integer that is not used in the cell and the neighboring cells.
- Theorem: The Greedy Algorithm is 2.5-competitive. This is optimal.
- Unfortunately, both upper bound and lower bound are too intricate to be presented here. But we can easily show that
- Theorem for lazy professors: The Greedy Algorithm is 3-competitive.
Online Call Control

- Problem: In a real GSM network, we have only a fixed amount of channels available. If there are more callers, we have to reject some.
- Simplification: We have only 1 frequency available.
- Problem Statement: We are given the hexagon graph with reuse distance 2. Callers arrive at cells in online fashion, that is, one after the other in an input sequence $\sigma$. We need to accept or reject each caller, such that there is at most 1 caller in a cell and its 6 neighboring cells. We assume that calls have infinite duration (which is the same as assuming that all calls have the same duration).
- Benefit: The benefit of the algorithm is the number of callers we accept.
- Competitive Analysis: If $\rho \cdot \text{benefit}_{\text{ALG}}(\sigma) \geq \text{benefit}_{\text{OPT}}(\sigma)$ for all input sequences $\sigma$ and an optimal offline algorithm OPT, then the Algorithm ALG is called $\rho$-competitive.

The Greedy Algorithm for Online Call Control

- Algorithm: When a new call arrives, it is accepted whenever possible.
- Theorem: The Greedy Algorithm is 3-competitive.
- Problem of algorithm is obvious already with the first call: If we do not accept the call, we are not at all competitive (because it might be the only call); if we accept the call might have to discard 3 calls in the neighboring calls later.

A Randomized Algorithm for Online Call Control

- It was long believed that the greedy algorithm is the best possible.
- New idea: Maybe randomization helps. Don’t accept every call that you might accept.
- Problem: Maybe adversary presents the same cell over and over until we (randomly) accept and then presents the 3 callers in the neighboring cells.
- Solution: If once a caller was (randomly) rejected in a cell, we should not accept any caller anymore in this cell (we mark the cell).

The randomized algorithm is $2.97$-competitive.
- Remarks:
  - For randomized algorithms, we use the expected benefit.
  - An improved version of the algorithm is $2.651$-competitive.
  - The algorithm can be generalized and is $27/28 \cdot \Delta$-competitive.
Logical Channels

- Traffic Channel TCH: For speech and data
  - Full rate TCH/F (22.8 kbit/s), Half rate TCH/H (11.8 kbit/s)
  - Speech codec needed 13 kbit/s – remaining bandwidth is used for strong error correction TCH/FS; now some use TCH/HS
  - For data there are TCH/F4.8, TCH/F9.6, and TCH/F14.4

- Control Channel CCH
  - Broadcast Control Channel BCCH: global variables in cell (such as hopping scheme, frequencies, frequencies of neighbor cells, etc.)
    - Frequency Correction Channel FCCH, Synchronization Channel SCH
  - Common Control Channel CCCH
    - Paging Channel PCH, Random Access Channel RACH (slotted Aloha!)
  - Dedicated Control Channel DCCH: Bidirectional
    - Stand-alone Dedicated Control Channel SDCCH (for stations without TCH, with only 782 bit/s), Slow Associated Dedicated Control Channel SACCH (for each station), Fast Associated Dedicated Control Channel FACCH (in case of handover)
Mobile Terminated Call

1: calling a GSM subscriber
2: forwarding call to GMSC
3: signal call setup to HLR
4, 5: request MSRN from VLR
6: forward responsible MSC to GMSC
7: forward call to current MSC
8, 9: get current status of MS
10, 11: paging of MS
12, 13: MS answers
14, 15: security checks
16, 17: set up connection

Mobile Originated Call

1, 2: connection request
3, 4: security check
5-8: check resources (free circuit)
9-10: set up call

MTC/MOC

MS MTC BTS MS MOC BTS
- paging request
- channel request
- immediate assignment
- paging response
- authentication request
- authentication response
- ciphering command
- ciphering complete

- $\text{BTS}_{\text{old}}$ $\text{BTS}_{\text{new}}$

MS

Security in GSM

- Security services
  - access control/authentication
    - user $\rightarrow$ SIM (Subscriber Identity Module): secret PIN (personal identification number)
    - SIM $\rightarrow$ network: challenge response method
  - confidentiality
    - voice and signaling encrypted on the wireless link (after successful authentication)
  - anonymity
    - temporary identity TMSI
      - (Temporary Mobile Subscriber Identity)
      - newly assigned at each new location update (LUP)
      - encrypted transmission
- 3 algorithms specified in GSM
  - A3 for authentication ("secret", open interface)
  - A5 for encryption (standardized)
  - A8 for key generation ("secret", open interface)

GSM - authentication

- 3 algorithms specified in GSM
  - $K_i$, RAND
  - 128 bit
  - 128 bit

- SRES
  - 32 bit

- A3
  - "secret"

- A3 and A8 available via the Internet

- network providers can use stronger mechanisms

- $K_i$: individual subscriber authentication key
- SRES: signed response
GSM - key generation and encryption

Data services in GSM: HSCSD

- Data transmission standardized with only 9.6 kbit/s
  - advanced coding allows 14.4 kbit/s
  - not enough for Internet and multimedia applications
- HSCSD (High-Speed Circuit Switched Data)
  - already standardized
  - bundling of several time-slots to get higher AIUR (Air Interface User Rate)
    (e.g., 57.6 kbit/s using 4 slots, 14.4 each)
  - advantage: ready to use, constant quality, simple
  - disadvantage: channels blocked for voice transmission

Data services in GSM: GPRS

- GPRS (General Packet Radio Service)
  - packet switching
  - using free slots only if data packets ready to send
    (e.g., 115 kbit/s using 9 slots temporarily)
  - standardization 1998, introduced 2000
- GPRS network elements GSN (GPRS Support Nodes)
  - GGSN (Gateway GSN)
    - interworking unit between GPRS and PDN (Packet Data Network)
  - SGSN (Serving GSN)
    - supports the MS (location, billing, security)
  - GR (GPRS Register)
    - user addresses

GPRS quality of service
